Aim: Apply Reference Resolution Technique on the given Text input.

Objective: Understand the importance of resolving references and implementing reference resolution for the given text input.

Theory:

Coreference resolution (CR) is the task of finding all linguistic expressions (called mentions) in a given text that refer to the same real-world entity. After finding and grouping these mentions we can resolve them by replacing, as stated above, pronouns with noun phrases.

<p>"I voted for Trump because he was most aligned with my values", John said.</p> <p>The original sentence</p>
<p>"John voted for Trump because Trump was most aligned with John's values", John said.</p> <p>The sentence with resolved coreferences</p>

Coreference resolution is an exceptionally versatile tool and can be applied to a variety of NLP tasks such as text understanding, information extraction, machine translation, sentiment analysis, or document summarization. It is a great way to obtain unambiguous sentences which can be much more easily understood by computers.

torch.optim as optim
```

+ Code

+ Text

▼ Sample data (context and senses)

```
data = [
    (["The", "bank", "by", "the", "river", "is", "steep."], "financial_institution"),
    (["I", "walked", "along", "the", "river", "bank", "yesterday."], "river_bank"),
]
```

▼ Create a vocabulary

```
vocab = set(word for context, _ in data for word in context)
word_to_idx = {word: idx for idx, word in enumerate(vocab)}
idx_to_word = {idx: word for word, idx in word_to_idx.items()}
```

▼ Map sense labels to integers

```
sense_labels = list(set(label for _, label in data)) sense_to_idx =
{sense: idx for idx, sense in enumerate(sense_labels)} idx_to_sense =
{idx: sense for sense, idx in sense_to_idx.items()} Convert data to
```

▼ tensors

```
data_tensors = [(torch.tensor([word_to_idx[word] for word in context]), torch.tensor(sense_to_idx[sense])) for context, sense in
```

```
data] Define the LSTM-based WSD model
```

```
class WSDModel(nn.Module):
    def __init__(self, vocab_size, embedding_dim, hidden_dim, sense_count):
        super(WSDModel, self).__init__()
        self.embedding = nn.Embedding(vocab_size, embedding_dim)
        self.lstm = nn.LSTM(embedding_dim, hidden_dim)
        self.fc = nn.Linear(hidden_dim, sense_count)

    def forward(self, context):
        embedded = self.embedding(context)
        lstm_out, _ = self.lstm(embedded.view(len(context), 1, -1))
        prediction = self.fc(lstm_out[-1])
        return prediction
```

Hyperparameters

```
vocab_size = len(vocab)
embedding_dim = 100 hidden_dim = 64
sense_count = len(sense_labels)
learning_rate = 0.001 epochs = 10
```

Initialize the model

```
model = WSDModel(vocab_size, embedding_dim, hidden_dim, sense_count)
```

Define the loss function and optimizer

```
criterion = nn.CrossEntropyLoss()
```

```
optim.Adam(model.parameters(), lr=learning_rate)
```

Training loop

```
def train(model, data, criterion, optimizer, epochs):
    model.train()
    for epoch in range(epochs):
        total_loss = 0
        for context, target_sense in data:
            optimizer.zero_grad()
            output = model(context)
            loss = criterion(output, target_sense.unsqueeze(0))
            # Add batch dimension to target
            loss.backward()
            optimizer.step()
            total_loss += loss.item()
        print(f"Epoch {epoch + 1}/{epochs}, Loss: {total_loss / len(data)}")
```

Train the model

```
train(model, data_tensors, criterion, optimizer, epochs)
```

Inference (predict senses for new contexts)

```
with torch.no_grad():
    new_context = ["The", "bank", "charges", "high", "fees."]
    new_context = torch.tensor([word_to_idx.get(word, 0) for word in new_context])
    new_context = new_context.unsqueeze(0)
    # Add batch dimension
    predictions = model(new_context)
    predicted_label = torch.argmax(predictions).item()
    idx_to_sense[idx_to_sense[predicted_label]]
    print(f"Predicted sense: {idx_to_sense[predicted_label]}")
```

```
Predicted sense: river_bank
```

Conclusion:

LSTM (Long Short-Term Memory) networks have been applied to word sense disambiguation tasks effectively. By learning contextual information, LSTMs help determine the correct sense of a word within a given context. They capture dependencies between words and can differentiate polysemous words. However, the performance is influenced by the size of the training data and model architecture. Combining LSTMs with attention mechanisms or pre-trained word embeddings can further enhance disambiguation accuracy.
